Smart City Bike-Sharing — Power BI Snapshot Report

Scope: station-level snapshot dataset supplied for the assignment. This is an operational availability analysis, not a revenue or trip-performance analysis.

Station records	**2,856**	Contracts/cities	**25**	Open	**2,650**	Closed	**206**
Total stand capacity	**57,203**	Available bikes	**19,646**	Available docks	**32,118**	Capacity checks	**1,283**

Key findings

• The file contains 2,856 station records across 25 contract/city labels. 2,650 records are marked OPEN (92.8%); 206 are CLOSED (7.2%).

• Total listed capacity is 57,203 stands and the dataset reports 19,646 available bikes. The simple availability-to-capacity ratio is 34.3% (interpret cautiously because 1,283 rows fail the capacity reconciliation check).

• The largest contracts by station count are: lyon (448), toulouse (431), bruxelles-capitale (357), valence (278), seville (271).

• 1,283 rows do not satisfy Bike Stands = Available Bike Stands + Available Bikes. Investigate before using occupancy or capacity metrics for operational decisions.

Recommendations

• Create a data-quality exception table for capacity mismatches and validate whether Bike Stands includes bikes plus empty docks in this source.

• Use slicers for ContractName, Status, Banking and Bonus; add cards for station count, open/closed stations, capacity and available bikes.

• Add a station map using Latitude/Longitude and a bar chart ranking contracts by station count / available bikes.

• The assignment examples about revenue per km and revenue trends cannot be answered from this file: there are no revenue, trip distance, trip count or reliable historical snapshots. Obtain trip-level / financial data to address those questions.

Data quality note: no exact duplicate rows were found in the supplied worksheet; StationNumber is repeated across records, so treat this as a station snapshot / multi-contract extract rather than assuming station number is globally unique.
